[First underwater carpet cloak realized, with metamaterial](#)

[Nanowerk, 05MAY2017](#)

An acoustic cloak is a material shell that can control the propagation direction of sound waves to make a target undetectable in an acoustic system. The parameters of the cloak shell in the design of new acoustic structures are too complex for practical use. Researchers in China adopted a scaling factor and simplified the structure of the carpet cloak using layers of brass plates featuring small channels filled with water to construct the model cloak. This material possesses effective anisotropic mass density in long-wavelength regimes. In tests, the cloaked object successfully mimicked the reflecting plane and was imperceptible to sound detection. [OPEN ACCESS TECHNICAL ARTICLE](#)

[3-D printers open new design space for wireless devices](#)

[Physorg.com, 04MAY2017](#)

A team of researchers in the US (Duke University, University of Michigan) has demonstrated the expanded degrees-of-freedom made available by 3D metamaterial, by designing, fabricating, and testing a 3D-printed unit cell with a broadband permittivity as high as 14.4. The presented method not only allows reliable and convenient fabrication of microwave metamaterials with high conductivity but also opens the door to exploiting the third dimension of the unit cell design space to achieve enhanced electromagnetic properties. [Discovery of new transparent thin film material could improve electronics and solar cells](#)

[Nanowerk, 05MAY2017](#)

An international team of researchers (USA - University of Minnesota, Washington University, Lawrence Berkeley National Laboratory, UC Berkeley, Singapore) developed a new transparent conducting thin film by growing a BaSnO_3 thin film replacing elemental tin source with a chemical precursor of tin. The precursor enhanced the chemical reactivity and greatly improved the metal oxide formation process. With high conductivity and wide bandgap, the new material could lead to smaller, faster, and more powerful electronics, as well as more efficient solar cells. [OPEN ACCESS TECHNICAL ARTICLE](#)

Physicists demonstrate photonic hypercrystals for control of light-matter interaction

Science Daily, 05MAY2017

A team of researchers in the US (City University of New York, Purdue University) developed “photonic hypercrystals” (PHCs) that combine the large broadband photonic density of states provided by hyperbolic metamaterials with the light-scattering efficiency of photonic crystals. Quantum dots embedded in the PHCs enhance radiative rate (20×) and light outcoupling (100×). Such designer photonic media with complete control over the optical properties provide a platform for broadband control of light-matter interaction. [OPEN ACCESS](#) [TECHNICAL ARTICLE](#)

Thermodynamic disorder in GaN-based nanowires

Nanowerk, 03MAY2017

GaN-based p-i-n power devices based on nanowires are suitable for attenuators, high-frequency switches, as well as photodetector applications. Nevertheless, non-radiate recombination affects the performance of devices based on such nanowires. Researchers in Saudi Arabia observed an increasing trend in the amount of photoinduced entropy of the system above 250 K. Since the entropy of a system sets an upper limit on the operational efficiency of a photoluminescent device, the findings have applications in developing and fabricating more efficient devices. Water-repellent material sheds like a snake when damaged

Physorg.com, 03MAY2017

Most of the superhydrophobic surfaces developed so far haven't been strong enough to stand up to damage by sharp objects. To create a new material, researchers in Germany stacked three layers: a water-repellant film made with poly-1H,1H,2H,2H-perfluorodecyl acrylate (PFA) “nanograss” on the top, a water-soluble polymer in the middle and a superhydrophobic silicon nanograss film on the bottom. When they scratched the coating, and submerged the material in water, the top layer then peeled off like molted skin and floated away, exposing the bottom, water-repellent film. Although further work is needed to strengthen the top coating so that a scratch won't be able to penetrate all three layers, the researchers say it offers a new approach to creating self-cleaning and water-repellent materials. AUTONOMOUS SYSTEMS & ROBOTICS

BAM! The Behance Artistic Media Dataset for Recognition Beyond Photography

ArXiv, 27APR2017

To teach machines how to categorize images in ways that are valuable to humans, a team of researchers in the US (Cornell University, industry partner) collected a large-scale dataset of contemporary artwork and annotated the imagery with rich attribute labels for content, emotions, and artistic media. Researchers believe their dataset will be a good starting point for researchers wishing to study artistic imagery and relevant problems.

COMMUNICATIONS TECHNOLOGY

Building an Internet of Things

American Physical Society Focus, 05MAY2017

In April, the American Physical Society organized a conference on the Actualization of the Internet of Things in Monterey, California. Part of what's driving the IoT is the proliferation of high-quality detectors, such as cameras and chemical sensors. Topics addressed included, the need for new sensors, advanced computing, “brain” to process and interpret the colossal amounts of data that the IoT generates and the need for devices with enough room for self-protection hardware, but at a cost that companies are willing to swallow.

Internet of things sensors could connect via ambient radio waves

Eurekalert, 05MAY2017

Researchers at Disney Research devised an ultra-low-power ultra-wideband ambient backscatter system of sensors that transmits data to a central receiver by reflecting the ambient radio waves from commercial broadcasting systems that already bathe most office environments. Using multiple backscatter channels boosts the signal-to-noise ratio, substantially improves the sensitivity of the backscatter reader and decreases dead zones, substantially extends the range to 22 meters when using ambient signals from broadcast towers and 50 meters when using ambient signals generated by mobile phone up-link traffic. Future Defense Scientists Take on Challenge of Synthetic Biology

[Armed with Science](#), 04MAY2017

The DTRA Syn Bio Academies Challenge kicked off its inaugural year in 2016. The DoD has a broad interest in synthetic biology, and is investigating the field with a view toward both addressing potential security concerns and understanding how this field may be best engaged in the development of improved countermeasures, sensing, and production of specialty materials. It is critical to the development of the next generation of countermeasures to weapons of mass destruction.

ENERGY

Using sulfur to store solar energy

[Physorg.com](#), 05MAY2017

Working under the PEGASUS project funded by the EU, researchers in Germany are developing a solar absorber combined with a thermochemical solar power storage system based on elementary sulfur and sulfuric acid. The focused sunlight of the solar power plant supplies the process with the energy and temperature required to close the sulfur cycle and to convert sulfuric acid back into sulfur dioxide in the presence of catalysts. Compared to current concepts, this promises to reduce costs significantly. They will test the technology under real conditions.

Water, water, nowhere: Research indicates graphene could act as efficient and water-free hydrogen fuel cell membrane

[Physorg.com](#), 05MAY2017

The reliability of the hydrogen fuel cells is limited by the proton exchange membrane made of a polymer called Nafion, which only conducts protons when it has the right amount of water on it. Through computational modeling, a team of researchers in the US (University of Pittsburgh, New Mexico Tech) has shown that because of graphene's unique structure, it is well suited to rapidly conduct protons across the membrane and electrons across the circuit under anhydrous conditions. This would enable hydrogen fuel cell cars to be a more practical alternative vehicle. TECHNICAL ARTICLE

New catalyst for water splitting developed

[Science Daily](#), 03MAY2017

Water-splitting systems require a very efficient catalyst to speed up the chemical reaction that splits water into hydrogen and oxygen, while preventing the gases from recombining back into water. An international team of researchers (Saudi Arabia, China, USA - Stanford University, Japan) reports that molybdenum-coated platinum prevents back reaction and works well in realistic operating conditions. Molybdenum was the best-performing material in acidic media, where the conditions for hydrogen evolution are favorable. The findings have applications in electrocatalysis and photocatalysis devices. ENVIRONMENTAL SCIENCE

Scientists develop device to predict clear-sky turbulence for safer air travel[Physorg.com](#), 05MAY2017

Researchers in Russia suggest using a “muon hodoscope,” which traces muon trajectories in the atmosphere for detection of zones of possible turbulence. As muons pass through the atmosphere they lose energy, and their flow changes. The quantity of lost energy depends on characteristics of the atmosphere, electromagnetic fields, temperature, air rarity and water vapor content. They have a working stationary hodoscope called HURRICANE, and a mobile version of the detector. According to the researchers, using muon diagnostics, it is possible to predict the development of powerful atmospheric phenomena at heights of up to 15 km. It is only necessary to create a network of similar devices.

IMAGING TECHNOLOGY

Shape-changing fog screen invented[Science Daily](#), 05MAY2017

Researchers in the UK have invented MistForm which is roughly the size of a 39-inch TV screen and is formed of fog stabilised by curtains of air. Making use of shape reconstruction and 3D projection algorithms, MistForm adjusts its shape to better support user interaction, while removing any image distortion caused by projecting on moving, curved fog surfaces. The display is projected from above and motion trackers detect the user's movements and intentions, allowing the display to adapt accordingly. This has the potential to enable new forms of interaction and collaboration with computers, liberating users from fixed, static screens and opening whole new interactive spaces.

Engineering research focuses on bringing efficiency to network processes[Eurekalert](#), 03MAY2017

Recently it has been shown that energy required to control a dynamical complex network is prohibitively large when there are only a few control inputs. Researchers at the University of New Mexico show that by controlling the states of a subset of the nodes of a network, rather than the state of every node, while holding the number of control signals constant, the required energy to control a portion of the network can be reduced substantially. The energy requirements exponentially decay with the number of target nodes. They validated their conclusions in model and real networks to arrive at an energy scaling law to better design control objectives. **OPEN ACCESS TECHNICAL ARTICLE**

MATERIALS SCIENCE

Sandwiched between superconductors, graphene adopts exotic electronic states

Nanowerk, 05MAY2017

An international team of researchers (USA - MIT, Japan) found that a flake of graphene, when brought in close proximity with two superconducting materials, can inherit some of those materials' superconducting qualities. As graphene is sandwiched between superconductors, its electronic state changes dramatically, even at its center. Graphene's electrons, formerly behaving as individual, scattering particles, instead pair up in "Andreev states"—a fundamental electronic configuration that allows a conventional, non-superconducting material to carry a supercurrent. The graphene platform may be used for exploring Majorana fermions which are thought to arise from Andreev states and may be key particles for building powerful, error-proof quantum computers.

Study looks to ice for fabricating useful porous materials

Physorg.com, 03MAY2017

An international team of researchers (China, USA - University of Nebraska) report the discovery of an ion-specific effect on ice recrystallization. By simply changing the initial type and concentration of ions in an aqueous solution, the size of ice grains after recrystallization can be tuned from 27 to 277 microns. The ability of the ion to be incorporated into the ice phase plays a key role in the ultimate size of the ice grains after recrystallization. Using recrystallized ice crystals as templates, 2D and 3D porous networks with tunable pore sizes could be prepared from various materials, for example, NaBr, collagen, quantum dots, silver and polystyrene colloids. These porous materials are suitable for a wide range of applications in organic electronics, catalysis and bioengineering.

Super P carbon black for reversible lithium and sodium ion storage

Nanowerk, 03MAY2017

Super P carbon black (SPCB) is the most commonly used conducting additive in lithium/sodium ion battery electrodes to improve the electronic conductivity. After a comprehensive study of SPCB, an international team of researchers (China, the Netherlands) reports that it is largely amorphous and contains substantial structural disorder, i.e. low graphitization level, exhibits considerable capacity for both lithium and sodium ion storage, a high cycling stability and excellent rate capability. They demonstrated that SPCB achieves a higher capacity for lithium ion than sodium ion storage. The findings will

provide an essential reference for the research on lithium and sodium ion battery electrodes that utilize SPCB as a conductive additive. TECHNICAL ARTICLE

MICROELECTRONICS

Nanogaps in plasmonic gold wires enhance voltage when excited

Nanowerk, 08MAY2017

Researchers at Rice University induced a temperature gradient using laser to study the nanoscale characteristics of the Seebeck effect in a single metal on the nanoscale. They found that the excited electrons can create a photovoltage about a thousand times larger than what is seen if there is no gap. The research shows that thermocouples can be made of a single material, laser can act as a local heat source and the photovoltage can be a thousand times larger. The technique can be used in sensors and electronics.

NEUROSCIENCE

Mind Reading Algorithms Reconstruct What You're Seeing Using Brain Scan Data

MIT Technology Review, 06MAY2017

fMRI scans are noisy and the activity in one voxel is influenced by activity in other voxels. Correlation is computationally expensive. Researchers in China process the data using deep-learning techniques that handle nonlinear correlations between voxels more capably. They use 90 percent of the data to train the network to understand the correlation between the brain scan and the original image. They then test the network on the remaining data by feeding it the scans and asking it to reconstruct the original images. The research is important for creating better brain-machine interfaces.

S&T POLICY

NIH to limit the amount of grant money a scientist can receive

Nature News, 03MAY2017

NIH will restrict the amount of funding that an individual scientist can hold at any one time, on the basis of a point system. The latest NIH policy does not set a hard limit on the number of grants or the dollar amount of funding that an individual researcher can receive. According to NIH, because scientific discovery is inherently unpredictable, there are reasons to believe that supporting more researchers working on a diversity of biomedical problems, rather than concentrating resources in a smaller number of labs, might maximize the number of important discoveries that can emerge from the science they support.

SENSORS

New self-sustained multi-sensor platform for environmental monitoring

Physorg.com, 04MAY2017

A self-sustaining sensor platform is a core component for Internet-of-Things and smart-grid systems. Researchers in South Korea have developed a water-contact triboelectric nanogenerator which produces electrical energy, correlated with the repetitive squeezing and releasing of a water droplet. The circuit, integrated with the nanogenerator, harvests the energy and converts into binary codes to be displayed through LEDs powered by the gathered energy. The proposed platform would contribute to advanced sensing functions of a self-sustaining system for various targeted-ambient elements. TECHNICAL ARTICLE
